A parametric test is a test that assumes certain parameters and distributions are known about a population, contrary to the nonparametric one The parametric test uses a mean value, while the nonparametric one uses a median value The parametric approach requires previous knowledge about the population, contrary to the nonparametric approach

term "nonparametric" but may not have understood what it means. Parametric and nonparametric are two broad classifications of statistical procedures. The Handbook of Nonparametric Statistics 1 from 1962 (p. 2) says: "A precise and universally acceptable definition of the term 'nonparametric' is not presently available.

The applicability of parametric test is for variables only, whereas nonparametric test applies to both variables and attributes. For measuring the degree of association between two quantitative variables, Pearson's coefficient of correlation is used in the parametric test, while spearman's rank correlation is used in the nonparametric test.

A parametric method would involve the calculation of a margin of error with a formula, and the estimation of the population mean with a sample mean. A nonparametric method to calculate a confidence mean would involve the use of bootstrapping. Why do we need both parametric and nonparametric methods for this type of problem?

This is the main idea behind the development of an approach known, in the literature, as parametrically guided nonparametric estimation. Due to its promising bias reduction property, this approach has been investigated in different frameworks such as density estimation, least squares regression and local quasi-likelihood.
